1. AI-Assisted Tele-Triage Companion for ASHA/PHC Workers

Domain: Healthcare

Problem Statement

A single ASHA (community health worker) covers 1,000+ people with no clinical decision support tool, and poor rural internet connectivity makes cloud-dependent apps unusable in the field.

Objective

Build an offline-first mobile app that lets the worker enter symptoms and vitals by voice in a local language, with an on-device AI model instantly returning a red/yellow/green triage flag plus a referral note — syncing to the PHC dashboard only once connectivity returns.

Description

The core challenge is two-fold: (a) running a meaningful clinical decision-support model entirely on-device (no cloud call needed for the triage decision itself), and (b) handling voice input in regional languages reliably enough for a non-technical health worker to trust it. The referral note output should be simple enough that a PHC doctor can act on it without back-and-forth.

Dataset Required

NFHS-5 (National Family Health Survey), HMIS Standard Reports (MoHFW), WHO IMCI (Integrated Management of Childhood Illness) symptom guidelines, and AI4Bharat IndicASR for speech-to-text in Indian languages.
